Covered in this lecture

Bootstrap

Section 1

The Bootstrap

The Idea

The goal: quantify the uncertainty associated with a given estimator or statistical learning method.

The boostrap idiom

- Originally used as a saying meaning an impossible task, used sarcastically
- Now often used to imply that socioeconomic advancement is something everyone should be able to do

6/20

Or. Munch (MSU-CMSE) Wed, Oct 12, 2022

Today's class: Bootstrap on a simple modeling problem

- We wish to invest a fixed sum of money in two financial assets that yield returns of X and Y, respectively, where X and Y are random quantities.
- We will invest a fraction α of our money in X, and will invest the remaining 1α in Y.
- Since there is variability associated with the returns on these two assets, we wish to choose α to minimize the total risk, or variance, of our investment.

One can show.....

...that
$$Var(\alpha X + (1 - \alpha)Y)$$
 is minimzed by

$$\alpha = \frac{\sigma_Y^2 - \sigma_{XY}}{\sigma_X^2 + \sigma_Y^2 - 2\sigma_{XY}}$$

where

•
$$\sigma_X^2 = \operatorname{Var}(X)$$

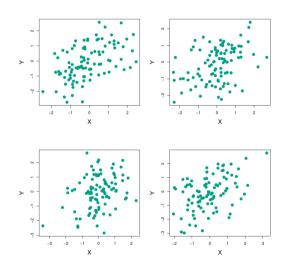

•
$$\sigma_Y^2 = \operatorname{Var}(Y)$$

•
$$\sigma_{XY} = \operatorname{Cov}(X, Y)$$

Get an estimate:

$$\hat{\alpha} = \frac{\hat{\sigma}_Y^2 - \hat{\sigma}_{XY}}{\hat{\sigma}_X^2 + \hat{\sigma}_Y^2 - 2\hat{\sigma}_{XY}}$$

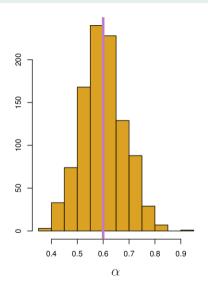

Simulated data

- Simulate data using

 - $\sigma_X^2 = 1$ $\sigma_Y^2 = 1.25$
 - $\sigma_{XY} = 0.5$
 - ▶ Implies $\alpha = 0.6$
- In each panel: Simulate 100 pairs of returns for investments
- Predict σ_X^2 , σ_Y^2 , and σ_{XY}
- $\hat{\alpha}$ prediction by panel: 0.576 0.543
 - 0.657 0.651

Resimulate: Rinse and repeat

- Simulate 100 data points 1,000 times
- \bullet Left: Histogram of predictions for α
- ullet Pink line: True value for lpha
- Mean over simulated values: $0.5996 = \bar{\alpha} = \frac{1}{1000} \sum \hat{\alpha}_r$

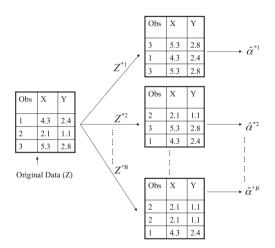

• St dev:
$$0.083 = \sqrt{\frac{1}{1000-1} \sum (\hat{\alpha}_r - \bar{\alpha})}$$

Coding part 1: Apprximate $\hat{\alpha}$ with simulated data

Dr. Munch (MSU-CMSE) Wed, Oct 12, 2022

So what's the problem?

The solution: Sample the data with replacement

Or. Munch (MSU-CMSE) Wed, Oct 12, 2022

Computation of error

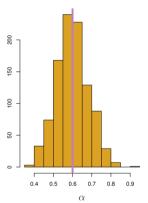

- Repeate procedure *B* times:
- Get B bootstrap data sets, $Z^{*1}, Z^{*2}, \dots, Z^{*B}$
- Get B bootstrap estimates $\hat{\alpha}^{*1}$, $\hat{\alpha}^{*2}$, ..., $\hat{\alpha}^{*B}$

Get standard error estimate:

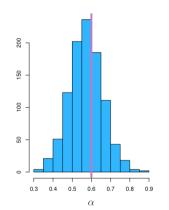

$$SE_B(\hat{\alpha}) = \sqrt{\frac{1}{B-1} \sum_{r=1}^{B} \left(\hat{\alpha}^{*r} - \frac{1}{B} \sum_{r'=1}^{B} \hat{\alpha}^{*r'} \right)^2}$$

Coding part 2: Resampling data

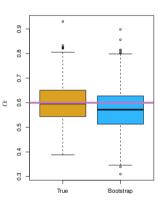

Back to the example

Resample version Predicted $SE(\hat{\alpha}) = 0.083$

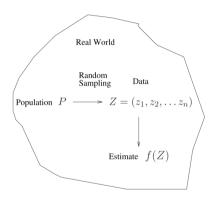

Bootstrap version Predicted $SE(\hat{\alpha}) = 0.087$

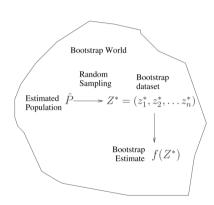

16 / 20

A general picture for the bootstrap

17 / 20

r. Munch (MSU-CMSE) Wed, Oct 12, 2022

TL;DR

- Start with data set of *n* points
- Sample *n* points with replacement to get data set Z^{*1}
- Use this to estimate whatever parameter we want $\hat{\mathcal{T}}^{*1}$
- Repeat B times to get estimates $\hat{T}^{*1}, \dots, \hat{T}^{*B}$
- Estimate standard error of our T estimate by

$$SE_B(\hat{T}) = \sqrt{\frac{1}{B-1} \sum_{r=1}^{B} \left(\hat{T}^{*r} - \frac{1}{B} \sum_{r'=1}^{B} \hat{T}^{*r'}\right)^2}$$

Boostrap vs Cross-Validation
